
LECTURE 6

MONTE CARLO SIMULATION BY EXCEL

(PART 2)

AGENDA

- Random number generation by Excel: other distributions
- What-if analysis

MONTE CARLO SIMULATION REVISIT WITH EXCEL

- Higgins Plumbing – Demand follows a general discrete distribution (table on right)
- Art's Newsstand – Demand follows uniform distribution, $U[30,150]$
- What if demand follows the normal distribution, or other distributions that you might have heard of?

| Heater Sales | Probability |
|--------------|-------------|
| 4 | 0.12 |
| 5 | 0.10 |
| 6 | 0.18 |
| 7 | 0.24 |
| 8 | 0.16 |
| 9 | 0.14 |
| 10 | 0.06 |
| Total | 1.00 |

CONTINUOUS UNIFORM DISTRIBUTION

- See “ $a+(b-a)\text{Rand}()$ ” worksheet.
- If a random variable follows a **continuous uniform distribution** $U[a, b]$, then all the values (real numbers, i.e. numbers with decimals) that lie between the lower limit a and the upper limit b are equally likely to be selected. To simulate such a random variable, we can use the formula

$$= a + (b - a) \times \text{RAND}()$$

- E.g. If you want real numbers between 3 and 9 inclusively, use

$$= 3 + (9 - 3) * \text{RAND}().$$

DISCRETE UNIFORM DISTRIBUTION

- See “RANDBETWEEN()” worksheet.
- If a random variable follows a **discrete uniform distribution** $U[a, b]$, then all the integers that lie between the lower limit a and the upper limit b are equally likely to be selected. To simulate such a random variable uses the formula:

$$= \text{RANDBETWEEN}(a, b) \quad \text{or} \quad = \text{INT}(a + (b - a + 1) * \text{RAND}())$$

- E.g. If you want whole numbers (or called integers) between 0 and 99, use

$$= \text{RANDBETWEEN}(0, 99) \quad \text{or} \quad = \text{INT}(100 * \text{RAND}())$$

BERNOULLI DISTRIBUTION

- See “Bernoulli” worksheet
- **Bernoulli distribution** - 2 outcomes, A and B: $Bern(p)$
 - A occurs with probability p , and B with probability $1 - p$.
 - Use the IF function: $=IF(RAND() < p, A, B)$
- **Binomial distribution** - The result of n independent Bernoulli random variables.
 - Count the number of times outcome A occurs (versus B).
- E.g. A customer purchases a chocolate ice cream with 55% probability, and strawberry ice cream with probability 45%
 - Customer purchases a chocolate ice cream:
 $=IF(RAND() < 0.55, "chocolate", "strawberry")$
 - If 10 customers arrive, then the # of customers purchasing a chocolate ice cream follows a Binomial distribution: $Bin(n, p)$

NORMAL DISTRIBUTION

- See “Normal” worksheet
- **Normal Distribution:** To generate random numbers from a normal distribution with mean μ and standard deviation σ , use the NORM.INV function:
$$= \text{NORM.INV}(\text{RAND}(), \mu, \sigma)$$
- Grades, height, weight, etc.
- E.g. To generate a random number from the normal distribution with mean = 10 and standard deviation = 5, use

$$= \text{NORM.INV}(\text{RAND}(), 10, 5)$$

SIMULATING PROBABILITY DISTRIBUTIONS IN EXCEL

| To SIMULATE | USE BUILT-IN EXCEL FORMULA |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| Random number between 0 and 0.9999... | =RAND() |
| Continuous uniform distribution between a and b | = $a+(b-a)*\text{RAND}()$ |
| Discrete uniform distribution between a and b | =INT($a+(b-a+1)*\text{RAND}()$) or =RANDBETWEEN(a,b) |
| Normal distribution: Mean = μ ; Standard deviation = σ | =NORM.INV(RAND(), μ, σ) |
| Bernoulli distribution Two outcomes: A and B, probability of A = p | =IF(RAND()< p ,A,B) |
| Discrete general distribution Range 1 = Cell range containing lower limits of the random number intervals Range 2 = Cell range containing the variable values | =LOOKUP(RAND(), Range 1, Range 2) |

EXAMPLE 1: ABC AIRLINE

- ABC Airline provides a daily six-passenger flight to Myrtle Beach. The fare of a one-way ticket is \$79, which is not refundable under no-show. The probability distribution of daily demand for such a flight and the probability distribution of no-shows (who forfeit their fares) are given in the tables on the next slide.
- The current booking policy of ABC is to oversell by three tickets. If more than 6 customers show up, then ABC must refund the fares of the extra tickets and compensate each of them \$100 in cash.
- The fixed cost of each flight is \$350, regardless of the number of passengers ($= 0, 1, \dots$, or 6).
- Question:
 - a. Simulate ABC's profit.
 - b. Investigate the outcomes where ABC oversells by 0, 1, 2, 3, 4, or 5 tickets. What are your recommendations?

EXAMPLE I: ABC AIRLINE

- See “ABC Airline” worksheet.

| Demand | Probability |
|--------|-------------|
| 5 | 0.05 |
| 6 | 0.11 |
| 7 | 0.20 |
| 8 | 0.18 |
| 9 | 0.16 |
| 10 | 0.12 |
| 11 | 0.10 |
| 12 | 0.08 |

| No-shows | Probability |
|----------|-------------|
| 0 | 0.15 |
| 1 | 0.25 |
| 2 | 0.26 |
| 3 | 0.23 |
| 4 | 0.11 |

EXAMPLE 1: ABC AIRLINE

- Step 1: # of tickets sold → REVENUE
 - = $\text{minimum}(\text{demand}, \text{flight capacity} + \text{overbooking policy})$
- Step 2: # of unhappy customers → COSTS
 - = $\text{maximum}(0, \text{\# of customers who show up} - \text{flight capacity})$
 - **\# of customers who show up** = # of tickets sold - # of no-shows
- Step 3: Profit
 - Revenue = $\$79 \times \text{\# of tickets sold}$
 - Overbooking cost = $(\$100 + \$79) \times \text{\# of unhappy customers}$
 - Profit = revenue – overbooking cost – fixed cost

EXAMPLE 1: ABC AIRLINE

- B3: number of accepted reservations = capacity (6)+ number of overbooking (3)
- B4: actual demand =`LOOKUP(RAND(),F6:F13,D6:D13)`
- B5: number of reservations taken =`MIN(B3,B4)`
- B6: number of no shows =`LOOKUP(RAND(),F16:F20,D16:D20)`
- B7: number of passengers that show up =`B5-B6`
- B8: number of seats short =`MAX(B7-F27,0)`
- B9: revenue = 79 × actual reservation accepted (B5)
- B10: overbooking cost =`B8*(100+79)`
- B11: profit = revenue – overbooking cost – fixed cost

USE DATA TABLE TO REPLICATE MULTIPLE RUNS

- One idea: “Press F9” (run the base model) many times, and track the results (metric).
- A better way to do this is via the Data Table function.
- **Step 1:** Create a table with two columns.
 - 1st column: Simulation runs “1, 2, 3, ...” (number of run).
 - 2nd column: Name the metric and reference to the cell containing the metric.

| | | |
|----|-----------------------------------|---------------|
| 6 | Number of no-shows = | 0 |
| 7 | Number of customers show up = | 9 |
| 8 | Seats short = | 3 |
| 9 | Revenue = | 711.00 |
| 10 | Overbooking cost = | 537.00 |
| 11 | Profit for flight = | (176.00) |
| 12 | | |
| 13 | Based on 1 replication: | |
| 14 | Average profit = | (176.00) |
| 15 | | |
| 16 | Based on 500 replications: | |
| 17 | Average profit = | 145.13 |
| 18 | P(Profit>=\$200)= | 42% |
| 19 | | |
| 20 | Simulation runs | Profit |
| 21 | 1 | (176.00) |
| 22 | 2 | 361.00 |

Description of
metric

Reference to
metric cell B14

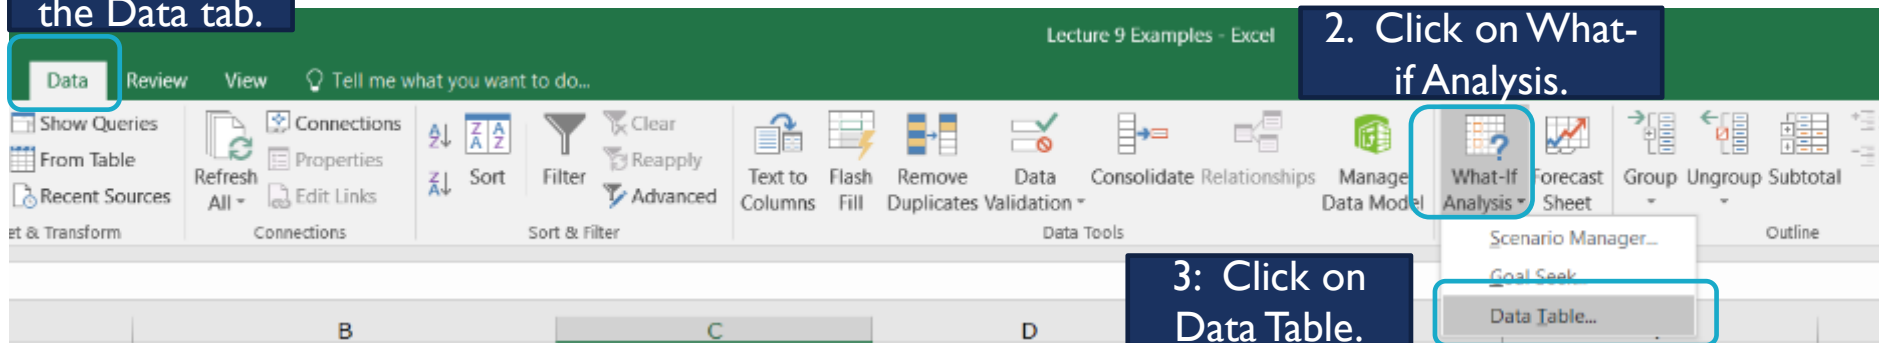

USE DATA TABLE TO REPLICATE MULTIPLE RUNS

- **Step 2:** Highlight the table with the metric reference as the top line. If we wanted to have 500 runs in the previous example, you would select cells A21:B520.
- **Step 3:** Ask Excel to fill in the table.

1. Click on the Data tab.

2. Click on What-if Analysis.

3. Click on Data Table.

USE DATA TABLE TO REPLICATE MULTIPLE RUNS

- **Step 3 (cont'd):** In the Data Table options, specify a reference to an empty cell! Then, click “OK.”

| | | |
|----|----------------------------|--------------------|
| 13 | Based on 1 replication: | |
| 14 | Average profit = | =B11 |
| 15 | | |
| 16 | Based on 200 replications: | |
| 17 | Average profit = | =AVERAGE(B21:B220) |
| 19 | | |
| 20 | Simulation runs | Profit |
| 21 | 1 | =B14 |
| 22 | 2 | |
| 23 | 3 | |
| 24 | 4 | |
| 25 | 5 | |
| 26 | 6 | |
| 27 | 7 | |
| 28 | 8 | |

Row input is blank.

Enter a cell reference of a cell that is not used in the model.

EXAMPLE I: ABC AIRLINE

- Analysing the result
 - What is the probability that profit will be \$200 or more?
 - Use of COUNTIF()
- What is the optimal overbooking policy?
 - Scenario Manager

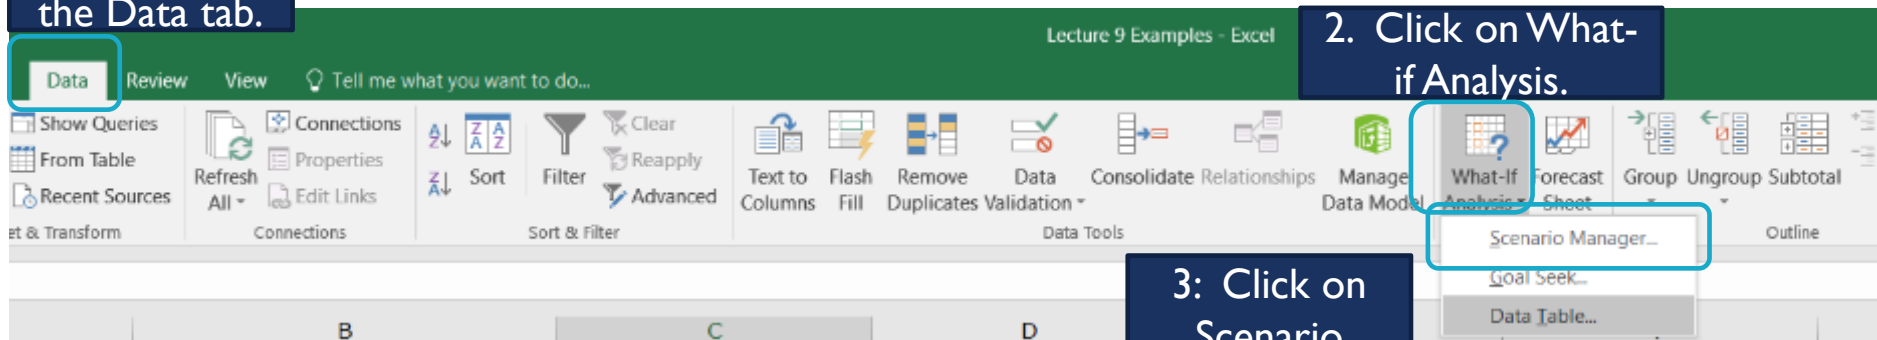

USE SCENARIO MANAGER TO INCLUDE DECISIONS

- We use “Scenario Manager” to decide the optimal “overbooking level” to maximize the expected profit

1. Click on the Data tab.

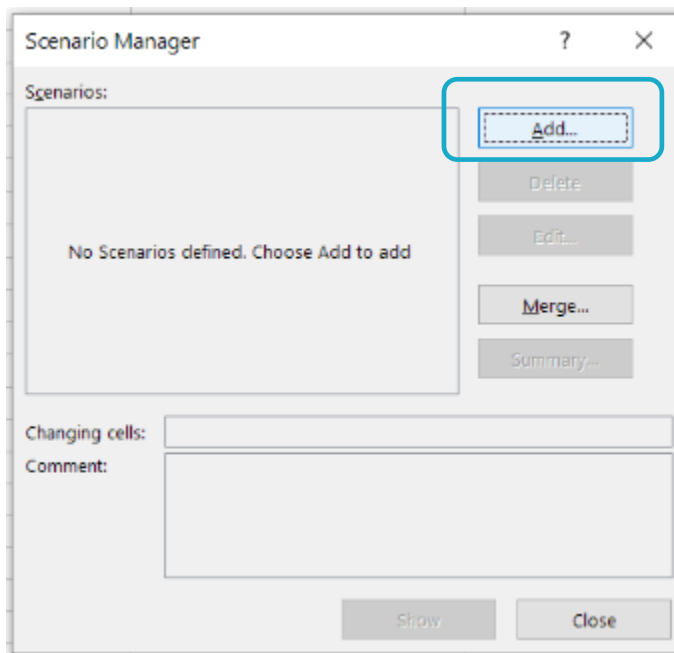

2. Click on What-If Analysis.

3. Click on Scenario Manager.

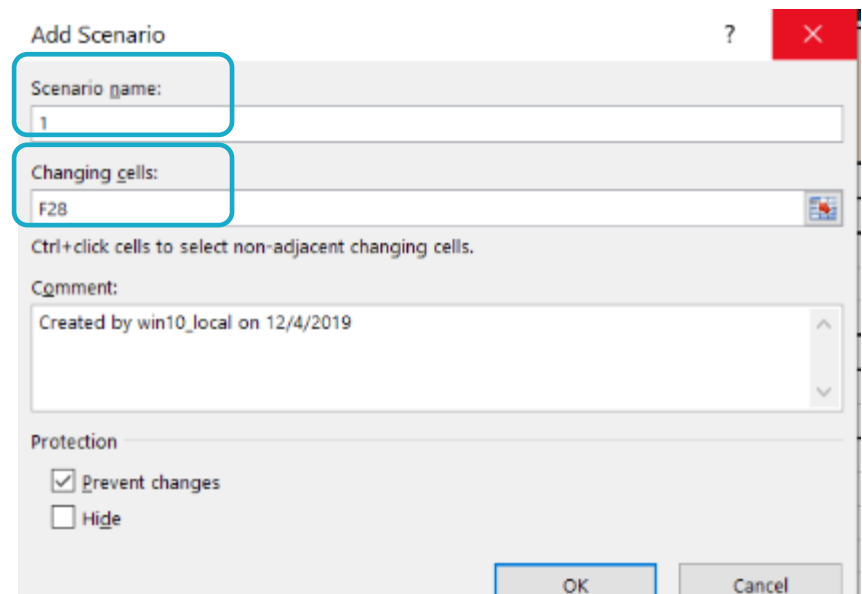

USE SCENARIO MANAGER TO INCLUDE DECISIONS

Step 1: Add Scenario.

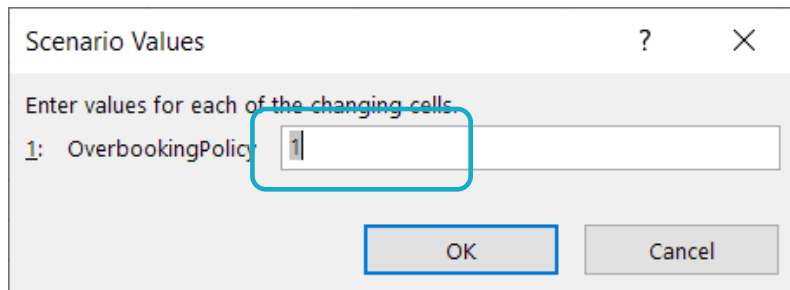

Step 2: Give “Scenario name” & specify “Changing cells”.

USE SCENARIO MANAGER TO INCLUDE DECISIONS

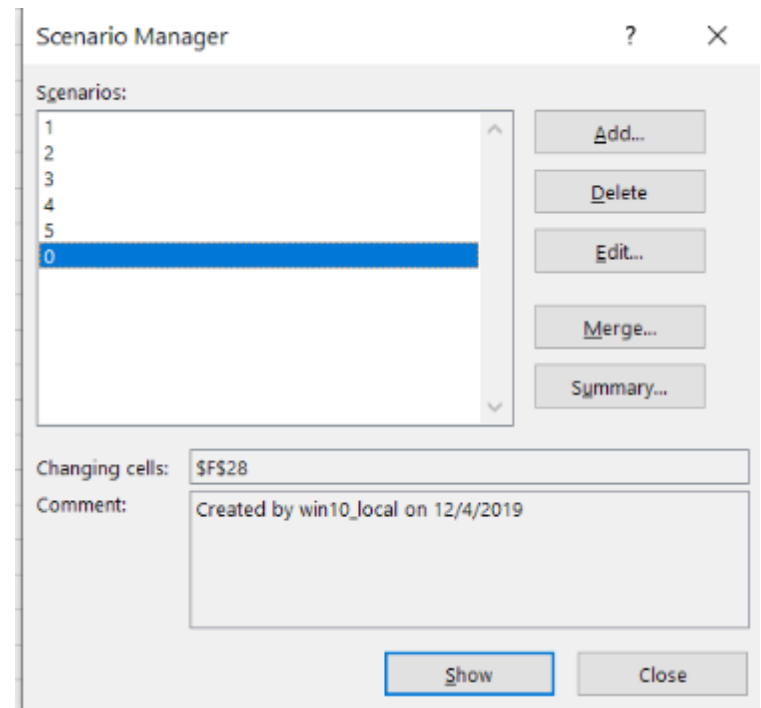

Step 3a: Enter value for each “Change cells”.

The "Scenario Values" dialog box is shown. It has a title bar with a question mark and a close button. The main text says "Enter values for each of the changing cells:". Below this, there is a list of changing cells. The first item is "1: OverbookingPolicy" followed by a text input field containing the value "1". At the bottom, there are "OK" and "Cancel" buttons.

| Changing Cell | Value |
|----------------------|-------|
| 1: OverbookingPolicy | 1 |

Step 3b: Add more scenarios if needed.

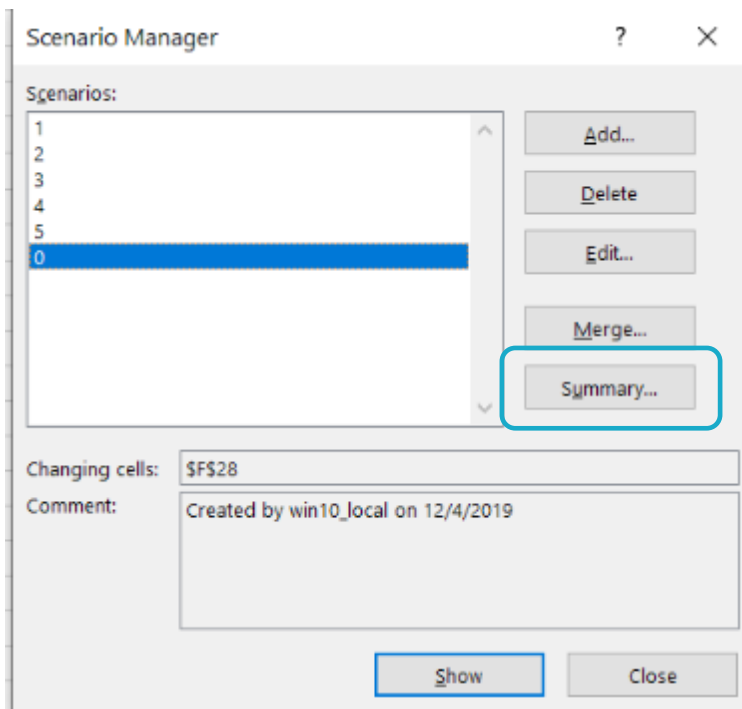

The "Scenario Manager" dialog box is shown. It has a title bar with a question mark and a close button. The main area is titled "Scenarios:" and contains a list of scenarios. The first scenario is "1" and the second is "2". The third scenario, "3", is selected and highlighted in blue. To the right of the list are buttons for "Add...", "Delete", "Edit...", "Merge...", and "Summary...". Below the list, there is a "Changing cells:" field containing "\$F\$28" and a "Comment:" field containing "Created by win10_local on 12/4/2019". At the bottom, there are "Show" and "Close" buttons.

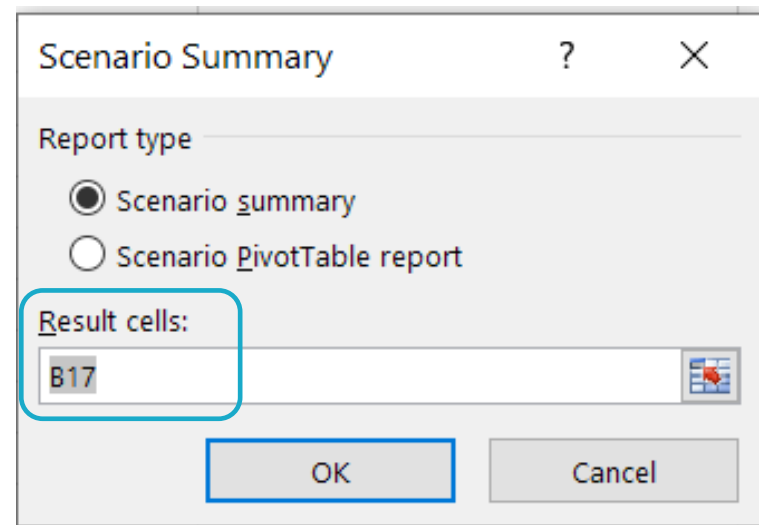

| Scenario | Changing cells | Comment |
|----------|----------------|-------------------------------------|
| 1 | \$F\$28 | Created by win10_local on 12/4/2019 |
| 2 | | |
| 3 | | |

USE SCENARIO MANAGER TO INCLUDE DECISIONS

Step 4: Click “Summary” to run the defined scenarios

Step 5: Specify “Result cells” to report. In this case, our “average” profit cell.

USE SCENARIO MANAGER TO INCLUDE DECISIONS

| 1 2 | | A | B | C | D | E | F | G | H | I | J | K |
|-----|--|---|---|---|---|---|---|---|---|---|---|---|
| 1 | | | | | | | | | | | | |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |
| 4 | | | | | | | | | | | | |
| 5 | | | | | | | | | | | | |
| 6 | | | | | | | | | | | | |
| 7 | | | | | | | | | | | | |
| 8 | | | | | | | | | | | | |
| 9 | | | | | | | | | | | | |
| 10 | | | | | | | | | | | | |
| 11 | | | | | | | | | | | | |
| 12 | | | | | | | | | | | | |
| 13 | | | | | | | | | | | | |

| Scenario Summary | | | | | | | |
|-------------------|--------|--------|--------|--------|--------|--------|--------|
| Current Values: | | | 2 | 3 | 4 | 5 | 0 |
| Changing Cells: | | | | | | | |
| OverbookingPolicy | 3 | | 2 | 3 | 4 | 5 | 0 |
| Result Cells: | | | | | | | |
| AvgProfit | 145.11 | 162.79 | 171.70 | 152.28 | 119.17 | 118.53 | 121.31 |

Notes: Current Values column represents values of changing cells at time Scenario Summary Report was created. Changing cells for each scenario are highlighted in gray.

THEORY: THE ANALYTICAL APPROACH

- Profit is a function of overbooking decision n , uncertain demand d , and no-shows s .
- $\Pi(n, d, s)$ = profit for a fixed n , realized observation of demand d , and no-shows s .
- Maximizing expected profit for different overbooking decisions, assuming independence of d, s :

$$\max_n E_{d,s}[\Pi(n, d, s)|n] = \max_n \sum_d \sum_s \Pi(n, d, s) \times Prob(d) \times Prob(s).$$

Scenario manager: Compute $E[\Pi(n, d, s)|n]$ over different values of n so that we can find the optimal n .

Data table: Fix n and compute $E[\Pi(n, d, s)|n]$ by running many simulation runs

- $Prob(\text{profit} \geq \$200 | n)$ is found by summing the joint probability, $Prob(d) \cdot Prob(s)$, over all pairs of (d, s) that satisfies $\Pi(n, d, s) \geq \$200$.

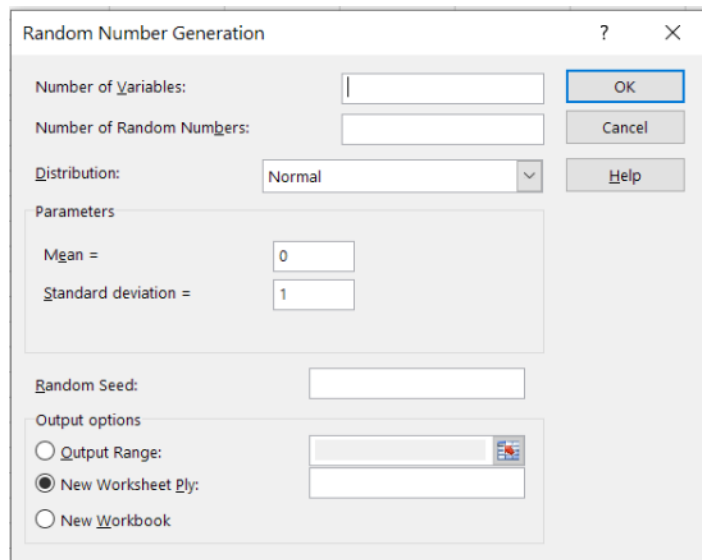

DEVELOPING THE SPREADSHEET MODEL

SUMMARY OF BASIC STEPS

- Use a random number to simulate a single run (or trial).
- Use the copy command or a data table (with blank column input cell) to simulate multiple runs in a single simulation (or replication).
- Calculate summary measures based on the outcomes of runs and create relevant graphs.

MORE ON RANDOM NUMBER IN EXCEL

- How to generate random numbers associated with a given distribution?

SUMMARY

- Generating random numbers from different probability distributions.
- Using simulation to identify decision which optimizes some expected value function.
